SEPTIC SYSTEM MAINTENANCE

Inside a septic tank, there are three layers. The top layer is the scum layer where organic material floats to the surface. Bacteria in the septic tank biologically convert this material to a liquid. The middle layer is the effluent layer where mostly clear water will be found. This clear water is the only layer that should enter your absorption area. The bottom layer is the sludge layer. This layer is where the inorganic or inert solid materials and the by-products of bacterial digestion sink.

The undigested sludge in the bottom of the tank should be treated regularly to keep the system healthy and functioning. Systems that build up a heavy deposit of sludge must be pumped, depending on usage and tank size. If the sludge is not removed periodically, it will eventually carry over into the leach field and cause the field to fail.
